Chapter 1

Introduction

Does anyone trust the news anymore? Not according to the latest Gallup Poll, which showed that only 4 in 10 Americans believe that mass media does a good job of reporting the news “fully, fairly, and accurately.” It’s a major decline since the poll was first taken in 1999, back when more than half (55%) of Americans believed the news was trustworthy [8].

And the trend has been steadily downward: in short, the majority of Americans have had little to no trust in mass media news coverage since 2007: a discouraging view for a tumultuous time in journalism.

But beyond frustrated readers and reporters, why does distrust in the news matter? For one, media bias—or at the very least, the *belief of* a biased media bias—may have a significant impact on the practice of democracy. A 2006 study from Georgetown University shows that those with more negative attitudes towards the news tend to be more highly influenced by their partisan prior beliefs and less by contemporary issues and messages when voting [5]. This implies that distrust of media plays a large role in the polarization of American politics.

In light of the upcoming 2016 elections, this thesis explores perceptions of media

trust and fairness in coverage of the presidential candidates. Claims of media bias and favoritism are especially high-stakes in election years, where trust has been shown to plummet [8]. And in this election cycle, cries of bias have been especially loud: Analysis at the New York Times showed that the news media gave Republican candidate Donald Trump a \$1.9 billion advantage in free publicity, an amount 190 times as much as paid advertising [3].

In this thesis, we examine some of the factors that contribute to the perception of media bias. In particular, how does the *content* of a story (reading level and vocabulary) affect the reader versus the *context* (publication and author)?

We break down the larger question of media bias in two dimensions: trust and fairness in reporting, and examine the role of language in influencing the reader. Although studies have been conducted to both examine the psychological effect of wording on believability and the impact of media brands and bias, separating and comparing these two factors remains largely unexamined [10, 4]

Two studies are performed: a preliminary and main experiment to collect reader's perceptions of news stories through crowdsourcing. We manipulate the source of the story to examine effects of media brands on the reader, and also compare trust and fairness rankings between high and low reading level stories.

Although the general consensus of mistrust is clear, perception of media bias is a complex phenomenon to dissect, as it combines social and psychological effects with the traits of the story itself. This thesis hopes to shed new light on understanding what motivates readers' trust and distrust of news media.

Chapter 2

In Media We ... Trust?

Despite the news media ecosystem’s rapid evolution in the past decade, the question of fairness in reporting remains a valued one. Although counterarguments for subjective reporting exist (Glenn Greenwald, most famous for his coverage of whistleblower Edward Snowden’s leaks, said that “All journalism is a form of activism. Every journalistic choice necessarily embraces highly subjective assumptions—cultural, political or nationalistic—and serves the interests of one faction or another”), fair treatment of subjects and sources remain a central tenant to most publications [1].

But an attempt at fairness on the side the reporter is not always perceived in equal effect under the eyes of the reader. Presenting contradictory facts to a reader’s beliefs can even sometimes *strengthen* their oppositions to it, a concept known as “motivated skepticism” [9].

In this section, we explore the theories behind three main potential sources of media distrust: In addition to the characteristics of the reader, we examine the source of the story and its use of language.

2.1 Why Does Media Trust Matter?

2.2 How is Media Trust Formed?

2.2.1 The Role of the Reader

It comes as no surprise that our own political stances have a significant effect in our perceptions of bias in the media.

2.2.2 The Role of Media Brands

2.2.3 The Role of Language

Chapter 3

Metrics for Measuring Trust

3.1 Computing Reading Level

3.1.1 Flesch-Kincaid Readability Tests

In this study, we focus primarily on the Flesch-Kincaid (F-K) tests for estimating text readability. Originally developed for the U.S. Navy in 1975 for assessing the difficulty of technical manuals, the F-K reading level corresponds roughly to U.S. grade level and the reading ease score is inversely proportional to the grade level on a scale from 0 to approximately 120 [?].

We chose the F-K tests over other comparable ones due to its popularity in educational assessment and other applications, including in legislation. For example, it is required by law in Florida that life insurance policies have a Flesch reading ease of 45 or greater (less than 12th grade in reading level) [?]. The F-K tests are also bundled in many common word processing services, including Microsoft Office Word. As a comparison, basic article analysis is also computed using the Gunning fog index (see Section 5.2.1).

The formula for Flesch reading ease is as follows:

$$206.835 - 1.015 \left(\frac{\text{total words}}{\text{total sentences}} \right) - 84.6 \left(\frac{\text{total syllables}}{\text{total words}} \right)$$

And for reading grade level:

$$0.39 \left(\frac{\text{total words}}{\text{total sentences}} \right) + 11.8 \left(\frac{\text{total syllables}}{\text{total words}} \right) - 15.59$$

The two formulas are not directly comparable due to the difference in weighting factors. For ease of metaphor, we use the grade level tests in our analysis. Syllable length is highly weighted in this formula, so it is possible to generate a story of very high reading level that consists of a single word in a single sentence (the longest English word, *pneumonoultramicroscopicsilicovolcanoconiosi*, a type of lung disease, has a reading grade level of 197.2), which is a limitation of the method, since texts with polysyllabic words are not always necessarily more difficult to read.

4.2.2 Dataset

4.2.3 Survey

4.3 Analysis

4.4 Conclusions

4.5 Limitations

From our exploratory study on reading level effects, we were able to obtain a significant but weak effect between disclosing the source and the levels of trust marked by readers towards an article.

We also observed trends that suggested an interaction between disclosing the source and the reading level of a story.

However, the study faced several limitations: first, we did not obtain enough samples to show a statistically significant result for interactions between source and reading level.

Furthermore, multiple levels of independent variables (ie: 5 levels for input source) made modeling complex and the results less clear.

The dataset was also unbalanced and sparse (ie, because of large numbers of input

variables we did not have complete representation for each category, such as high, low, and mid-reading level stories for every outlet and topic). We tried to control for those factors by randomization, however it made more difficult to analyze specific correlations between source and trust.

To further explore the interaction between disclosing the source and the reading level of the story, we set up another crowdsourcing experiment on CrowdFlower, this time targeting this specific interaction, to see if there is a significant effect between the two, detailed in the following chapter.

Chapter 5

Media Brand Effects

5.1 Motivations

Following the limitations and patterns from the preliminary study, we designed a follow-up study to verify interactions between news source and reading level.

What were your main hypotheses? H1 H2

5.2 Experimental Design

For the second study, our experiment was revised to have a 4 x 2 mixed-factorial design. In this study, reading level of articles and candidates featured in the articles were treated as within-subject variables, and the source of the story between-subjects.

	Source: None	Source: AP	Source: Fox	Source: CNN
High Reading Level	Clinton, Cruz, Sanders, Trump	Clinton, Cruz, Sanders, Trump	Clinton, Cruz, Sanders, Trump	Clinton, Cruz, Sanders, Trump
Low Reading Level	Clinton, Cruz, Sanders, Trump	Clinton, Cruz, Sanders, Trump	Clinton, Cruz, Sanders, Trump	Clinton, Cruz, Sanders, Trump

Table 5.1: Main Study Design

This time, we reduced the number of stories to $N=8$, and also changed reading level from a 3-level to 2-level variable (low, high) for clarity.

Most significantly, since we observed some significant effect from disclosing source to the reader in Study 1, we added a manipulation in this experiment to further study the effect of revealing the source:

Following Baum’s research in showing the effects of media brands and reader bias by manipulating reported brands, all eight stories in Study 2 were in fact written by the Associated Press, however, we manipulated the source shown to the reader [4]. In group A, readers were shown the headline and text of the story with no other context. In group B, readers were additionally shown that the story was from the Associated Press (true label). In groups C and D, readers were shown that the story was from CNN and Fox News, respectively.

This setup was created to eliminate some of the confounding effects from using stories from different sources (writing style, focus of content, slant, etc.), while directly observing the effect of revealing a specific source to the reader. The Associated Press was chosen as the source of the stories as it is the highest circulation newswire service in the United States, and has 14,000 members that use its content [7]. Notably, both CNN and Fox News publish content in full or part from the Associated Press, although the specific stories chosen had not been published in full by either to avoid bias.

We removed the favorability question from Study 1 (as the 3-point scale did not yield significant results), instead asking the reader more directly about media bias by ranking the fairness of the story on a 5-point Likert scale. The trustworthiness question from Study 1 was kept, also on the same 5-point Likert scale.

5.2.1 Dataset

Eight stories were chosen for this study: two (high and low reading level) per candidate.

5.2.2 Survey

5.2.3 Quality Control

5.3 Analysis

5.4 Conclusions

How do your trustworthiness findings line up with the findings from Pew surveys and prior work? What hypotheses did you verify from prior work?

5.5 Limitations

Just 8 stories I know
